Overview

This work describes an improved risk assessment approach for analyzing safety designs in the battery energy storage system incorporated in large-scale solar to improve accident prevention and mitigation, via incorporating probabilistic event tree and systems theoretic analysis. The International Renewable Energy Agency predicts that with current national policies, targets and energy plans, global renewable energy shares are expected to reach 36% and 3400 GWh of stationary energy storage by 2050. NFPA is keeping pace with the surge in energy storage and solar technology by undertaking initiatives including training, standards development, and research so that various stakeholders can safely embrace renewable energy sources and respond if potential new hazards arise. Since this series was first issued, there have been at least sixteen further incidents of BESS failures¹ around the world that have resulted in fires and damage to property, although there are no reports of significant injuries. It identifies the hierarchical risk characteristics, described as "single cell failure to system-wide failure propagation. However, alongside these benefits, concerns persist regarding the safety and environmental impacts.
